Erosive-punctate dermatosis (EPD) is a rare skin condition characterized by pruritic erythematous to purple-colored macules that were originally called depigmented eczema. EPD is caused by pigment-associated keratinocytes at affected sites. The exact cause of EPD is unknown, but it may be caused by an infection or allergy to hair dye, contact adhesive tape, or medications. Physicians should be familiar with the presentation, risk factors, and treatment options of EPD. We report the first case of EPD caused by allergic contact dermatitis in a 16-year-old girl.A favorite among the brie-eating set, the \$13 offering from Pinnacle Cheese is made from the milk of grass-fed cows and boasts a slightly rubbery texture that's said to be a sign of good things to come. Too bad the apricot flavor tastes overwhelmingly of artificial food coloring. For the price, the small wedge (not sold in a resealable container) is a decent starter or snack. But the cheese is pricey in comparison to its small size. This is especially true if you share it with friends, as we did. A serving (enough to feed about two) retails for \$15, and a bigger container of 24 packs for \$1,440. If Pinnacle Cheese (www.pinnaclecheese.com) had brought a stronger product to market, perhaps its name would have been changed to Pinnacle Cheese Snacks.In many advanced optical signal processing applications, it is desired to use a light source having a broad spectrum or bandwidth. Broad spectrum sources, including super-continuum lasers, provide improved spectral signal processing because they allow optical filtering in the optical spectrum. However, the large intensity of the spectrum across the bandwidth causes phase fluctuations in the laser output that cause distortion and loss of signal. As shown in FIG. 1
